

intro to the
autocorrelation function (ACF)

in our family MONSTERS tend to be...

- A little similar to their parent and great-grandparent
- Very different from their grandparent
- Very similar to their great-great grandparent

FOR EXAMPLE:

THE autocorrelation function (ACF)

The ACF is a plot of autocorrelation between a variable and itself separated by specified lags (in our case, generations)

LET'S BUILD ONE!

At lag = 1, we find the correlation between
monsters and their **parent**.

They are somewhat positively correlated.

At lag = 2, we find the correlation between **monsters** and their **grandparent**.

Since they tend to be very different, we find a **negative correlation at lag = 2**.

At lag = 3, we find the correlation between **monsters** and their **great-grandparent**.

They are slightly positively correlated.

At lag = 4, we find the correlation between **monsters** and their **great-great grandparent**.

They tend to be very similar
(there is a positive correlation).

...and we continue finding the correlations as we increase the lag (generations) between the monsters...

in summary:

The autocorrelation function (ACF) tells us the correlation between observations and those that came before them, separated by different lags (here, monster generations)!
